Working with GitHub Remote Repositories

Back to: Microservices using ASP.NET Core Web API Tutorials

Working with GitHub Remote Repositories Using Visual Studio

When we work alone, a **local Git repository** is enough. But real-world software development is a **team activity**. Code must be shared, reviewed, and synchronized across multiple developers and machines. This is where **remote repositories**, especially **GitHub**, become essential.

What is a remote repository, and why do teams use it?

A **Remote Repository** is a repository stored on another location, usually on a server or cloud platform such as **GitHub**. It contains the same project history, branches, and commits, but it is available online, allowing multiple developers to access it.

Teams use a remote repository because:

- It acts as the **central shared codebase**
- Everyone can push their work to a common place
- Everyone can pull the latest updates from teammates
- It helps with collaboration, code review, and backup
- It supports workflows like pull requests, branch sharing, and deployment

Without a remote repository:

- Each developer only has their own local copy
- Sharing code becomes manual and difficult
- Team coordination becomes slow and risky

So, in real projects:

- **Local Repository** = your workspace
- **Remote Repository** = team's shared workspace

How to Create a New GitHub Remote Repository?

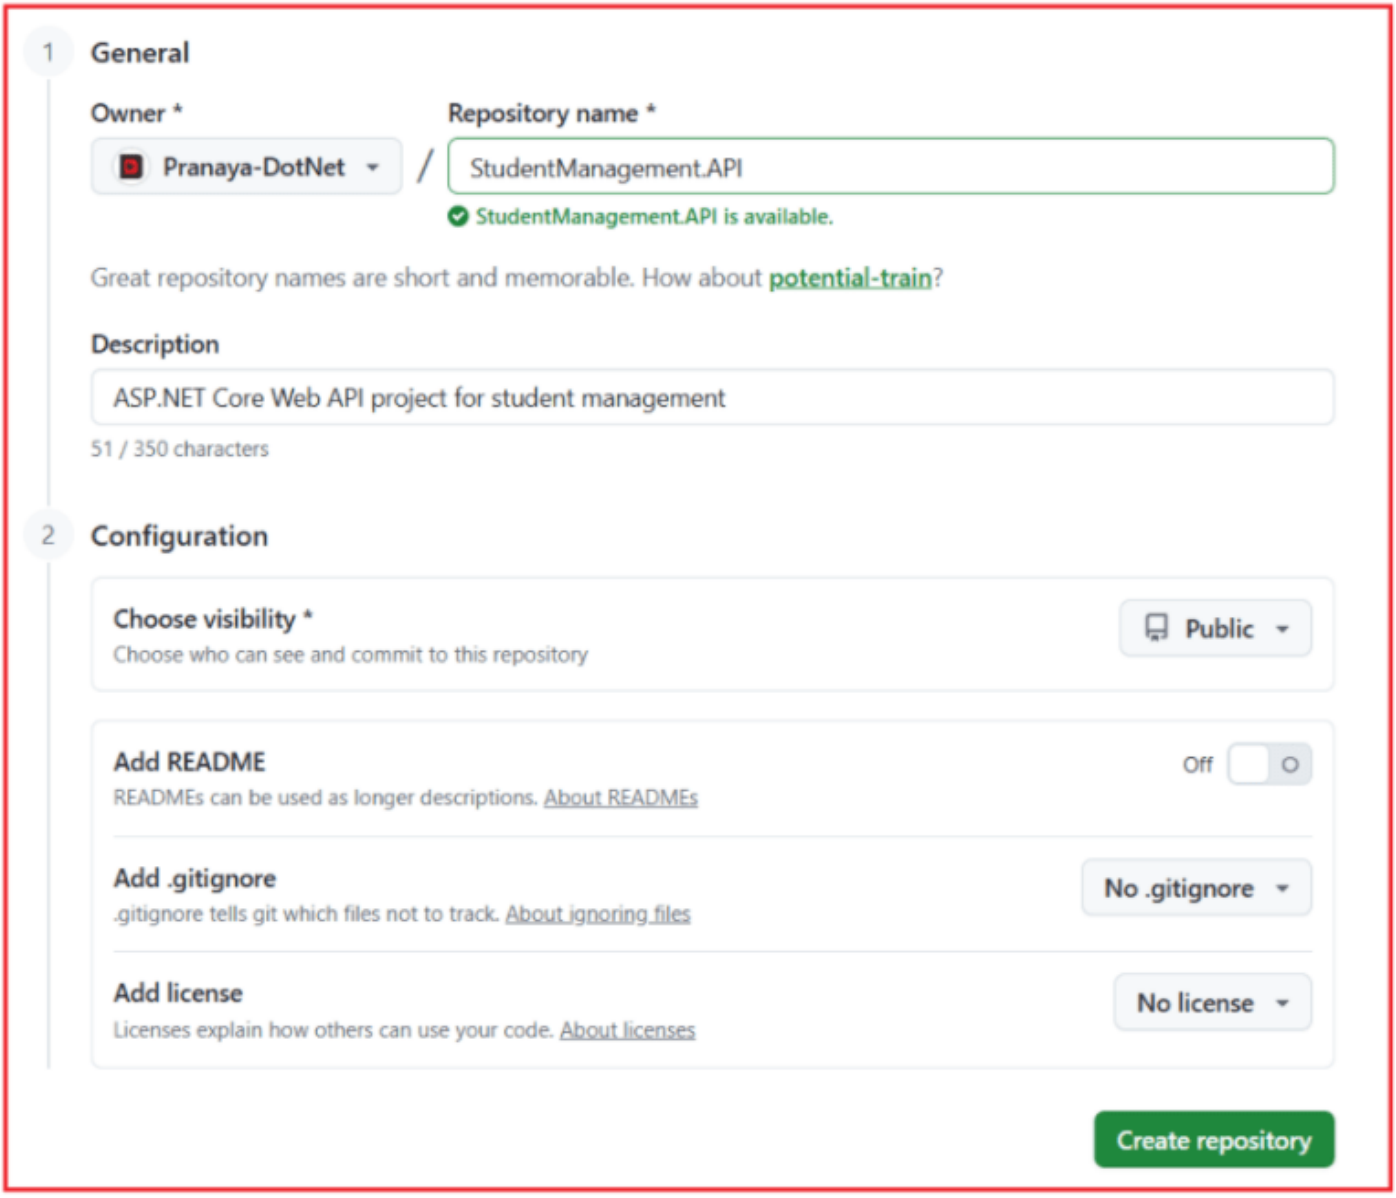
On GitHub, creating a new repository is done from the top-right **+** menu by choosing **New repository**. GitHub's docs describe this as the standard way to create a repository from the web UI.

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

Step-by-step:

- Open **https://github.com**
- Sign in to your GitHub account
- Click the **+** icon at the top-right
- Click **New repository**
- Enter a **Repository name**
- Choose **Public** or **Private**
- Click **Create repository**

For a better understanding, please have a look at the following image:

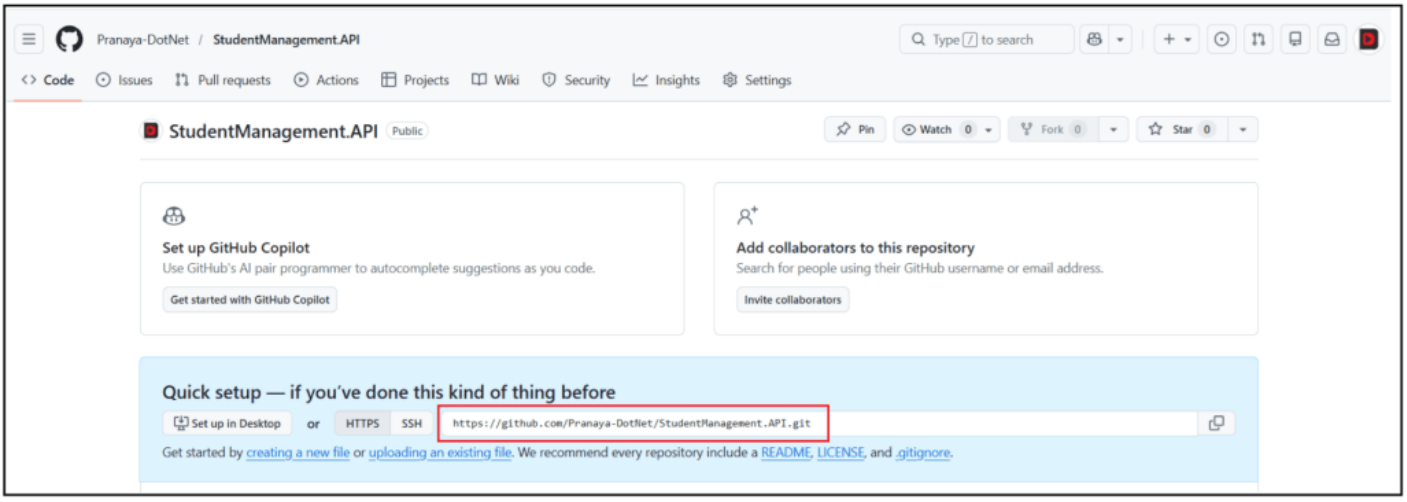


Settings:

Please provide the following:

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

- **Owner:** Keep your account (Pranaya-DotNet)
- **Repository name:** StudentManagement.API
- **Description:** Optional. You can leave it blank, or add something like: ASP.NET Core Web API project for student management
- **Choose visibility: Public**
- **Add README: Off**
- **Add .gitignore: No .gitignore**
- **Add license: No license**
- Then click **Create repository**. You should see the following. Please copy the repository URL.



Why are these options correct for us?

Because:

- We already have the project locally.
- Our local repo already has files and commit history.
- We only want an **empty remote repository** on GitHub

Public vs Private Repositories

A GitHub repository can be either **Public** or **Private**. This decides **who can see your code** on GitHub. When you create a new repository, GitHub asks you to choose one of these two visibility options. A **Public repository** can be viewed by anyone on the internet. A **Private repository** can only be viewed by you and the people you explicitly give access to.

What is a Public Repository?

A **Public Repository** is open for everyone to view. That means:

- Anyone can visit the repository page

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

- Anyone can see your files, commits, branches, and README
- Anyone can clone the repository to their machine

Public repositories are commonly used for:

- Open-source projects
- Learning projects
- Sample/demo projects
- Portfolios
- Code you want to share publicly

Example: If you create a public ASP.NET Core Web API project on GitHub, other developers can view your controllers, services, and project structure directly.

What is a Private Repository?

A **Private Repository** is restricted. That means:

- Only you can see it by default
- Only invited collaborators or team members can access it
- Other people cannot view or clone it without permission

Private repositories are commonly used for:

- Company projects
- Client work
- Personal projects not ready to share
- Projects containing business logic or sensitive code

Example: If your ASP.NET Core project is for a real client or internal company use, it should usually be private.

Which one should you choose?

Choose **Public** if:

- You want to share your code openly
- It is a learning/demo/open-source project
- You want others to view your work

Choose **Private** if:

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

- The project is personal or confidential
- It is the company/client code
- You do not want others to access it

How to Link Our Existing Local Visual Studio Repo to GitHub?

Because we already have a local repo, we usually do **not** clone first. Instead, we connect our existing local repo to the GitHub repo as a remote.

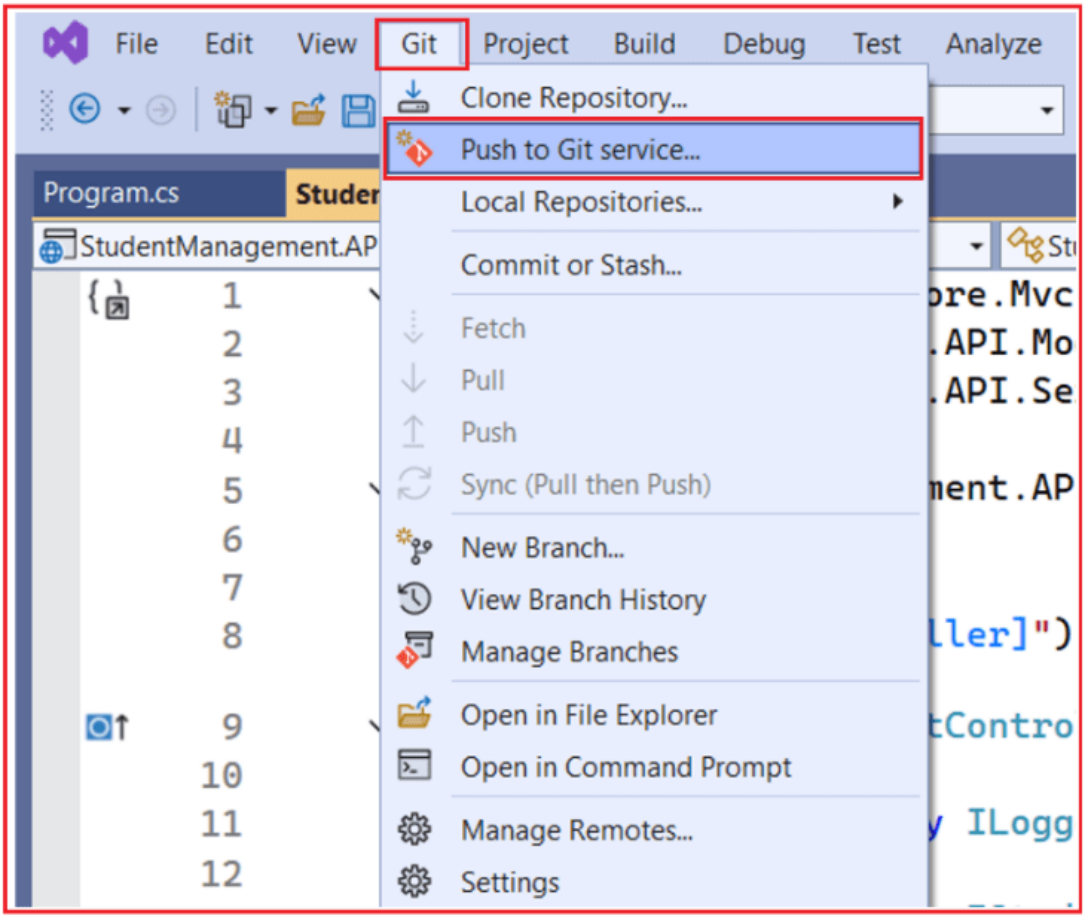
Step 1: Copy your GitHub Repository URL

On GitHub, open your new repository and copy the **clone URL**. It will look like:

- **https://github.com/Pranaya-DotNet/StudentManagement.API.git**

GitHub uses this URL as the remote address for your repo.

Step 2: In Visual Studio, click Git → Push to Git Service…

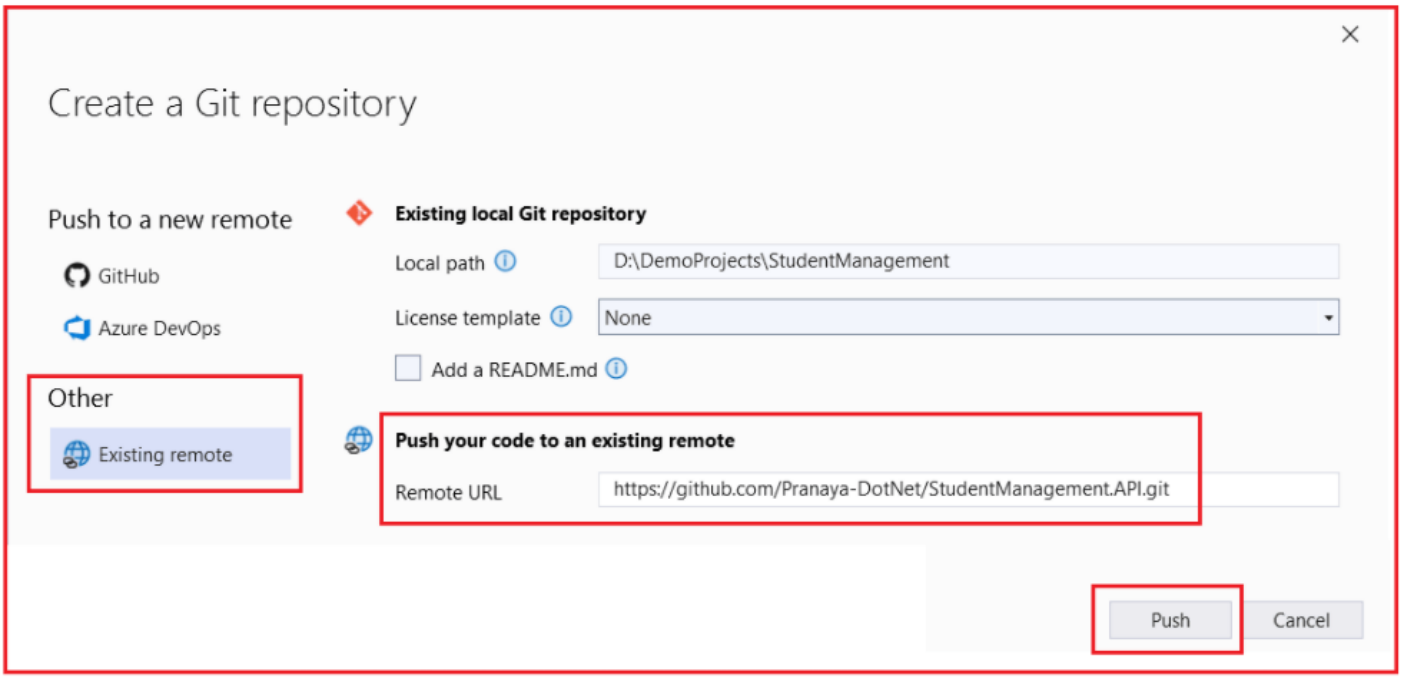


Step 3: In the Create a Git Repository Window

Choose:

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

- **Existing Remote**
- **License template: None**
- **Add a README.md: Leave unchecked**
- **Remote URL:** keep your GitHub repository URL as it is. **https://github.com/Pranaya-DotNet/StudentManagement.API.git**.
- Confirm the branch (usually main). Look at the **bottom-right corner** of Visual Studio. You will see the current branch name there.
- Click **Push**



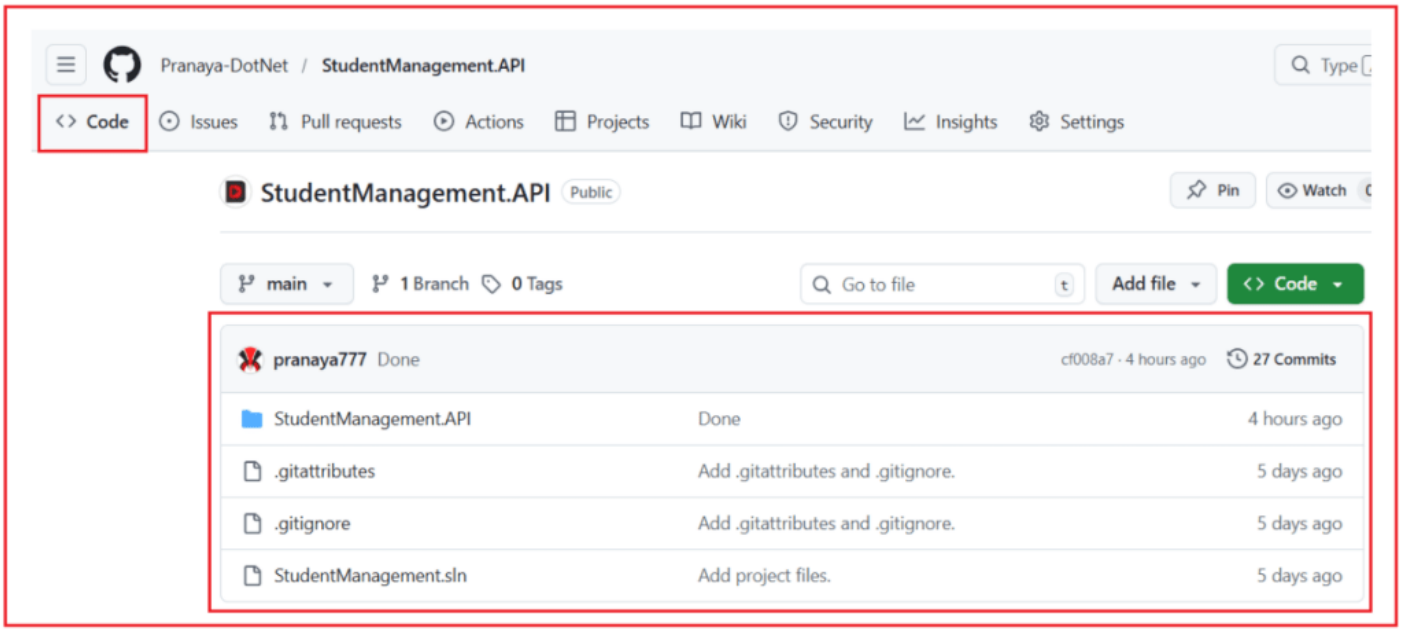
What is Visual Studio doing behind the scenes?

- Our local repo gets a remote named **origin**
- That origin points to our GitHub repo URL
- After that, Push/Pull work between local and GitHub

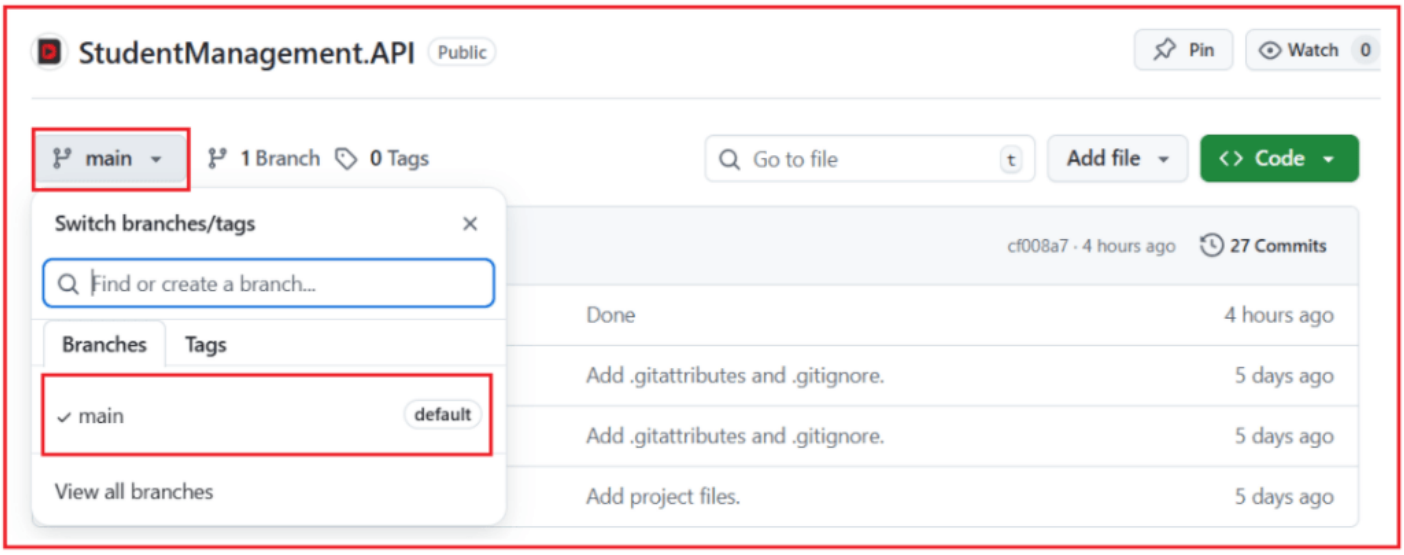
How to verify the Repo in GitHub after Push?

After you click **Push** in Visual Studio, verify it on GitHub. Open your repository page on GitHub. Check the **Code** tab (main repository page). Your project files and folders should now be visible there.

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF



Check the **Branch Dropdown** and make sure you are viewing the correct branch (usually main). GitHub's branch selector lets you view branches from the repository page.



Click the **commits/history** link for the repository (or open a file and use its history) to confirm your latest commit message appears. GitHub documents that you can view a repository's commit history from the commits page.

In simple words, open the GitHub repo, confirm your files appear under the **Code** tab, make sure the right branch is selected, and verify your latest commit is visible in the commit history.

What is Push?

Push means sending our local commits to the remote repository. Push sends only **committed changes**. Uncommitted changes are not pushed.

So, the flow is:

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

- Make changes
- Commit locally
- Push to GitHub

When we push:

- GitHub gets our latest commits
- Other developers can then pull our changes
- Our branch on GitHub is updated

Simple meaning: Push = Upload my local commits to GitHub

How to Push Your Existing Local Code to GitHub

A **push** sends our local commits to the remote repository.

Step-by-step in Visual Studio:

- First, make sure your files are committed locally
- Open **View** → **Git Changes**
- If you still have changed files:
    - Stage them
    - Enter a commit message
    - Click **Commit**
- Then click **Push (Git → Push)**

What happens:

- Visual Studio uploads your local commits
- GitHub receives them on the linked branch
- Your code now appears in the GitHub repository

Important: Only **committed** changes are pushed. Uncommitted edits stay only on your machine.

What is Pull?

Pull means bringing the latest changes from the remote repository into your local repository. When you pull:

- Git first gets the latest remote changes
- Then it merges those changes into your local branch

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

So, if another developer pushed code to GitHub, you use **Pull** to update your local copy.

Simple meaning: Pull = Download the latest changes from GitHub and update my local branch

How to Pull the Latest Changes from GitHub

A **pull** gets the latest changes from the remote repository and updates your local branch.

Step-by-step in Visual Studio:

- Open the project in Visual Studio
- Go to the **Git** menu
- Click **Pull**

What happens:

- Visual Studio downloads the latest commits from GitHub
- Then it merges them into your current local branch

Use Pull when:

- You start your workday
- Another developer has pushed code
- Your own branch on GitHub has new commits
- Before you push your own work

Difference between Push and Pull?

These two are in opposite directions.

- **Push:** Moves your local commits **from your computer to GitHub**
- **Pull:** Moves remote commits **from GitHub to your computer**

So:

- **Push = Local → Remote**
- **Pull = Remote → Local**

Why Pull Before Push?

You should usually **Pull before Push** because the remote repository may already contain new changes from other developers. If you push without pulling:

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

- Your local branch may be outdated
- GitHub may reject your push
- You may need to merge changes later under pressure

If you pull first:

- You get the latest code from teammates
- You resolve any conflicts locally
- Your push becomes smoother and safer

Simple team rule:

- Start work by pulling the latest changes
- Before the final push, pull again if needed
- Then push your commits

This reduces:

- Push rejection
- Merge surprises
- Team conflicts

What happens when Push is Rejected?

A push is usually rejected when the remote branch has commits that your local branch does not have.

This means:

- GitHub has a newer history
- Your local branch is behind
- Git will not let you overwrite the remote branch automatically

Common reason: Another developer pushed changes before you did.

What Git is protecting: Git is preventing accidental loss of remote commits.

What you should do:

- Pull the latest changes from GitHub
- Resolve conflicts if needed
- Commit the merge (if required)

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

- Push again

Simple meaning: Push rejected = your local branch is not up to date with the remote branch. Do not panic. This is a normal part of teamwork.

What is a Clone?

Clone means creating a full local copy of an existing remote repository. When you clone a GitHub repository:

- Git downloads all files
- Git downloads the commit history
- Git downloads branches and remote connection info
- A local Git repository is created on your machine

You usually clone when:

- You are joining an existing project
- The project already exists on GitHub
- You want a local working copy of that remote repository

Simple meaning: Clone = Download the remote project and set it up locally

How to Clone a GitHub Repository

A **clone** creates a full local copy of a remote repository.

Step-by-step in Visual Studio:

- Open Visual Studio
- Go to **Git** → **Clone Repository**
- Paste the GitHub Repository URL
- Choose the local folder
- Click **Clone**

What happens after cloning:

- The project is downloaded locally
- You can immediately pull, commit, and push to that repo (subject to permissions)

Conclusion

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

A remote repository is essential for team-based development because it gives everyone a shared, online version of the project. GitHub is where teams store and share code, while each developer continues to work safely in their own local repository. By understanding clone, push, pull, and origin, you understand the foundation of real-world Git collaboration.

In Visual Studio, all of this becomes much easier because the IDE gives you built-in options to connect to GitHub, publish your repository, pull the latest changes, push your commits, and resolve conflicts. Once your local repository is connected to GitHub, your day-to-day work becomes smoother, safer, and more professional.

🎥 Prefer Learning by Watching?

If you want a complete step-by-step understanding of Git Branching, Commit Best Practices, and Merge Conflict Resolution in ASP.NET Core, we’ve created a detailed video tutorial for you.

👉 Watch the full video here:
https://youtu.be/mFGYilvdHXY

In this video, you will see:
• Real-time branching using Visual Studio
• How to write professional commit messages
• Practical merge conflict resolution (with real examples)
• Clean workflow followed in real projects

Explore our developer-friendly HTML to PDF API Printed using PDFCrowd HTML to PDF

💡 Highly recommended if you are preparing for interviews or working in team-based development.

Don’t miss it — this will make your Git concepts crystal clear
